Rate-Distortion Autoencoders (RDAs)

Cross Entropy for Continuous Structured y

Cross entropy is a challenging objective for continuous structured values y such as images and sounds.

$$\Phi^* = \operatorname*{argmin}_{\Phi} \; E_{y \sim \text{pop}} \; - \ln p_\Phi(y)$$

$$\Phi^* = \operatorname*{argmin}_{\Phi} \; E_{\langle x, y \rangle \sim \text{pop}} \; - \ln p_\Phi(y|x)$$

GANs replace the cross-entropy loss with an adversarial discrimination loss.

Rate-Distortion Auto-Encoders (RDAs) and Variational Auto-Encoders (VAEs) use the cross-entropy objective more directly.

Rate-Distortion Autoencoders (RDAs)

A rate-distortion autoencoder (RDA) replaces differential cross-entropy loss with a compression rate and a reconstruction loss (distortion).

The primary example is lossy compression of images and audio.

We take the compressed object to be discrete — a file with a well defined length in bits.

Rate-Distortion Autoencoders (RDAs)

We compress a continuous signal y to a bit string (or other discrete object) $\tilde{z}_\Phi(y)$.

We decompress $\tilde{z}_\Phi(y)$ to $y_\Phi(\tilde{z}_\Phi(y))$.

We can then define a rate-distortion loss.

$$\mathcal{L}(\Phi) = E_{y \sim \text{Pop}} \; -\ln P_\Phi(\tilde{z}_\Phi(y)) + \lambda \text{Dist}(y, y_\Phi(\tilde{z}_\Phi(y)))$$

Here the rate is defined as a discrete cross-entropy.

L_2 Distortion

$$\mathcal{L}(\Phi) = E_{y \sim \text{Pop}} \; -\ln P_\Phi(\tilde{z}_\Phi(y)) + \lambda \text{Dist}(y, y_\Phi(\tilde{z}_\Phi(y)))$$

It is common to take

$$\begin{aligned} \text{Dist}(y, \hat{y}) &= ||y - \hat{y}||^2 \\ &= -\ln p(y|\hat{y}) + C \qquad \text{for a Gaussian density} \end{aligned}$$

We will ignore the log density interpretation and just call this distortion.

L_1 Distortion

$$\mathcal{L}(\Phi) = E_{y \sim \text{Pop}} \; -\ln P_\Phi(\tilde{z}_\Phi(y)) + \lambda \text{Dist}(y, y_\Phi(\tilde{z}_\Phi(y)))$$

Alternatively we have

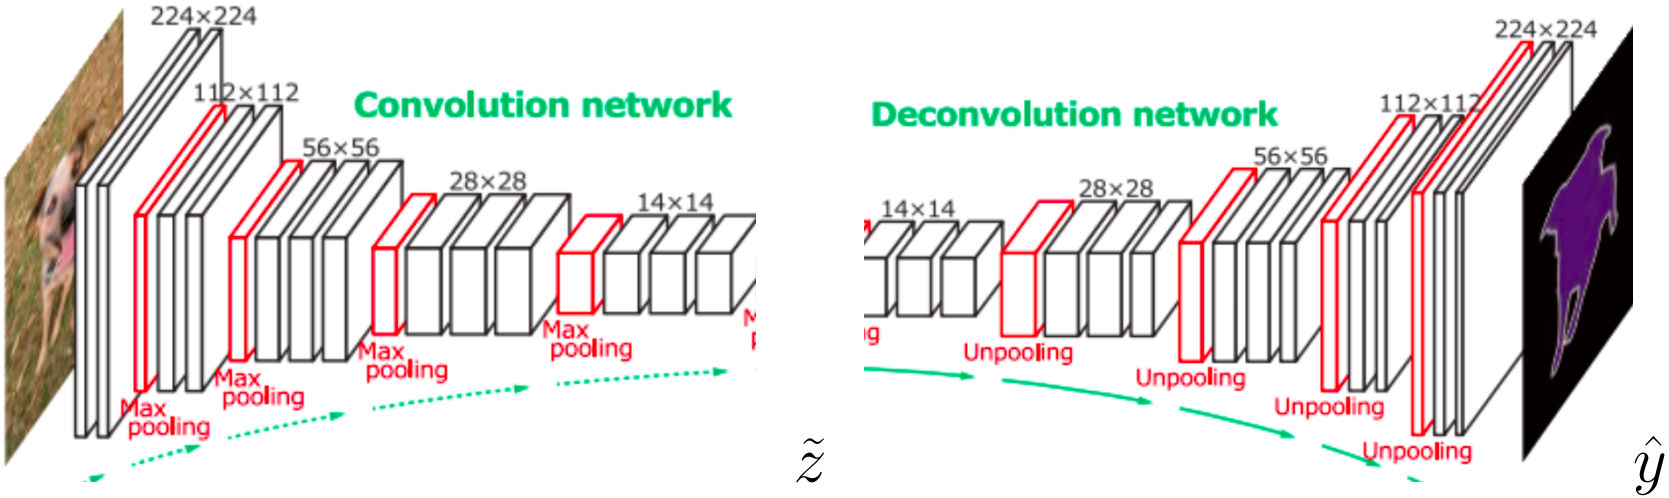
$$\begin{aligned} \text{Dist}(y, \hat{y}) &= ||y - \hat{y}||_1 \qquad\qquad (L_1) \\ &= -\ln p(y|\hat{y}) + C \;\text{ for a Laplace density} \end{aligned}$$

Again, we will ignore the log probability interpretation and just call this distortion.

CNN-based Image Compression

These slides are loosely based on

End-to-End Optimized Image Compression, Balle, Laparra, Simoncelli, ICLR 2017.



y $\tilde{z}$ $\hat{y}$

Rounding a Tensor

Take $z_\Phi(y)$ can be a layer in a CNN applied to image y. $z_\Phi(y)$ can have with both spatial and feature dimensions.

Take $\tilde{z}_\Phi(y)$ to be the result of rounding each component of the continuous tensor $z_\Phi(y)$ to the nearest integer.

$$\tilde{z}_\Phi(y)[x, y, i] = \lfloor z_\Phi(y)[x, y, i] + 1/2 \rfloor$$

Rate-Distortion Autoencoders (RDAs)

Since rounding is not differentiable, at training time we replace rounding by additive noise.

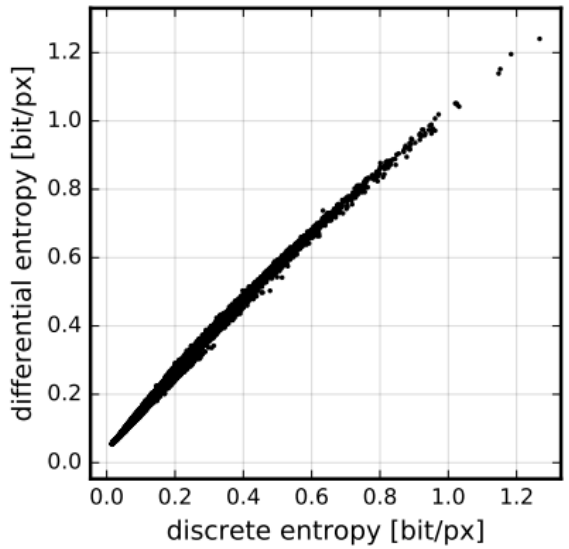
$$\Phi^* = \underset{\Phi}{\operatorname{argmin}} \; E_{y \sim \text{Train}} \; E_{\epsilon \sim [-1/2,1/2]^d} \begin{cases} -\ln p_\Phi(z_\Phi(y) + \epsilon) \\ \\ + \; \lambda \text{Dist}(y, y_\Phi(z_\Phi(y) + \epsilon)) \end{cases}$$

The continuous density $p_\Phi(z)$ is parameterized in a way that guarantees

$$p_\Phi(z) \approx P_\Phi(\tilde{z})$$

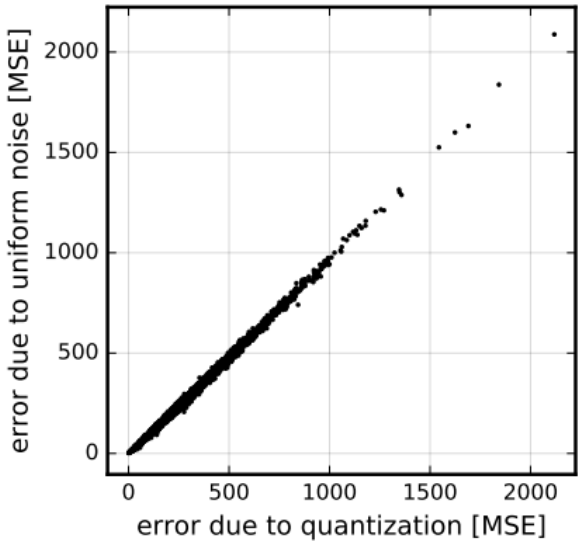
At test time we use rounding.

Rate: Differential Entropy vs. Discrete Entropy



Each point is a rate for an image measured in both differential entropy and discrete entropy. The size of the rate changes as we change the weight λ.

Distortion: Noise vs. Rounding



Each point is a distortion for an image measured in both a rounding model and a noise model. The size of the distortion changes as we change the weight λ.
